## AERODYNAMIC SYMBOLS.

### I. GENERAL

$m$	Mass
$t$	Time
$V$	Resultant linear velocity
$\Omega$	Resultant angular velocity
$\rho$	Density, or relative density
$\nu$	Kinematic coefficient of viscosity
$R$	Reynolds number, $R = lV/\nu$ (where $l$ is a suitable linear dimension)

Normal temperature and pressure for aeronautical work are  $15^{\circ}\text{C}$  and 760 mm. For air under these conditions  $\rho = 0.002378 \text{ slug/cu.ft.}$   $\nu = 1.59 \times 10^{-4} \text{ sq.ft/sec.}$

The slug is taken to be 32.2 lb. - mass.

$\alpha$	Angle of incidence
$\epsilon$	Angle of downwash
$S$	Area
$b$	Span
$c$	Chord
$A$	Aspect ratio, $A = b^2/S$
$L$	Lift, with coefficient $C_L = L/t\rho V^2 S$
$D$	Drag, with coefficient $C_D = D/t\rho V^2 S$
$\gamma$	Gliding angle, $\tan \gamma = D/L$
$L$	Rolling moment, with coefficient $C_L = L/t\rho V^2 bS$
$M$	Pitching moment, with coefficient $C_m = M/t\rho V^2 cS$
$N$	Yawing moment, with coefficient $C_n = N/t\rho V^2 bS$

### 2. AIRSCREWS.

$n$	Revolutions per second
$D$	Diameter
$J$	$V/nD$
$P$	Power
$T$	Thrust, with coefficient $k_T = T/\rho n^2 D^4$
$Q$	Torque, with coefficient $k_Q = Q/\rho n^2 D^5$
$\eta$	Efficiency, $\eta = TV/P = Jk_T/2\pi k_Q$

**SUMMARY.**—Predictions from work on rough pipes suggested that surface roughness would increase the drag of an aerofoil at high Reynolds numbers. Experiments have been carried out in the Compressed Air Tunnel on the aerofoil N.A.C.A. 0012, (a) with the usual finish, (b) with the surface chromium plated and (c) with the surface coated with carbondum powder to two degrees of roughness; and on the aerofoil R.A.F. 34, (a) with the usual finish, (b) with the entire surface roughened and (c) with only the back-half roughened. The tests were made at Reynolds numbers ranging from  $0 \cdot 16 \times 10^6$  to  $7 \cdot 2 \times 10^6$  and at angles of incidence up to  $28 \cdot 5^\circ$ . It was found that surface conditions had a large effect on maximum lift and on minimum drag at high Reynolds numbers.

*Maximum Lift.*—Maximum lift increases with Reynolds number. The effect of surface roughness on maximum lift is to cause the curve, plotted against Reynolds number, to diverge from that for a smooth aerofoil at a value of  $R$  which decreases as the roughness increases. Above that value of  $R$ , the maximum lift remains nearly constant. (Fig. 9 for N.A.C.A. 0012, Fig. 10 for R.A.F. 34.) Surface roughness thus decreases the maximum lift, the loss on  $C_{L_{max}}$  increasing as the roughness is increased. The two degrees of roughness caused a loss of 15 per cent. and 20 per cent. on maximum lift for N.A.C.A. 0012 at high values of  $R$ , and the coarser roughening caused a loss of 26 per cent. on  $C_{L_{max}}$  for R.A.F. 34. Roughening only the back-half of R.A.F. 34 caused no loss in maximum lift up to the highest value of  $R$  in the experiments.

*Minimum Drag.*—The minimum drag curve for a roughened aerofoil, plotted against Reynolds number, diverges from that for a smooth aerofoil at about the same value of  $R$  as for the maximum lift curves. The point of divergences agrees well with the predicted value. Above this point, the drag increases with increasing roughness. (Fig. 11 for N.A.C.A. 0012, Fig. 12 for R.A.F. 34.) The value of  $R$  at which the divergence occurs is higher when only the back-half of an aerofoil is roughened. Uniformly distributed excrescences of 0.0004 in. and of 0.001 in. on an 8 in. aerofoil increase the minimum drag at high Reynolds numbers by some 25 per cent. and 60 per cent. respectively.

*Further Developments.*—Chromium plating the aerofoil N.A.C.A. 0012 decreased the minimum drag by 5 per cent. and increased the maximum lift by 5 per cent., indicating that further improvements might be obtained with better finish. It is proposed to test an aerofoil with as fine a polish as can be obtained ; and also, for maximum lift, to experiment with different areas of roughness on the upper surface.

1. *Introductory.*—The effect of surface roughness on the behaviour of an aerofoil at high Reynolds numbers has been much discussed lately on account of its great importance in the design of high speed aircraft. The work of Nikuradse<sup>1</sup> on the resistance to flow in rough pipes, and the deductions from this work made by Prandtl and Schlichting<sup>2</sup> on the skin friction of rough plates, have suggested that at high Reynolds number a comparatively small degree of roughness may produce an important increase in profile drag. This is borne out in practice in tests made by Schrenk<sup>3</sup> and Ebert<sup>4</sup> on the profile drag of wings in flight.

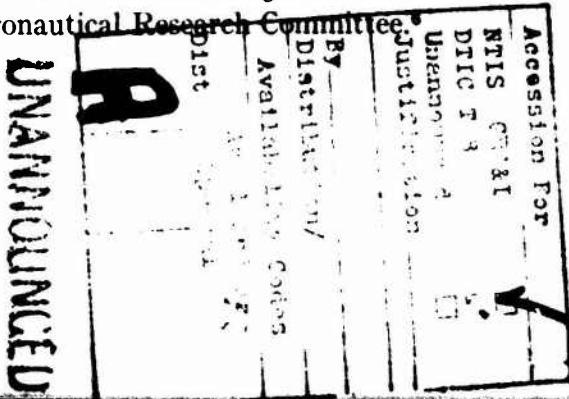

Measurements have been made in the Compressed Air Tunnel on two aerofoils with the usual finish and with the surface roughened. On an aerofoil of symmetrical section, N.A.C.A. 0012, tests have been completed over a large range of Reynolds number with the usual finished surface, with the surface coated with a paste of carborundum powder and lacquer to two degrees of roughness and with the aerofoil chromium plated in an attempt to improve the surface. An aerofoil of section R.A.F. 34 has been tested with the whole surface roughened in a similar way and with only the back-half roughened, to compare with results previously obtained on this section<sup>5</sup>.

It is not pretended that these roughened surfaces represent at all accurately any full scale roughness likely to be realised in practice. The object of the tests was merely to establish the general effect of roughness by Compressed Air Tunnel tests, and to correlate the results in a general way with the predictions from Nikuradse's work on rough pipes.

Roughening the entire surface in these cases has no effect at Reynolds numbers below  $1 \times 10^6$  and this accounts for the negative results obtained by experimenters on models tested in atmospheric tunnels. At higher values of Reynolds number, surface roughness increases the minimum drag and decreases the maximum lift. The effects are discussed in detail below.

The original aim of the experiments on the aerofoil N.A.C.A. 0012 was to provide data for a direct comparison of results from the two tunnels operating with compressed air, the Variable Density Tunnel at Langley Field and the Compressed Air Tunnel of the National Physical Laboratory. It is known that the turbulence in the two tunnels differs considerably and any discrepancies in the results may be attributed to turbulence. Turbulence is known to have a large effect on maximum lift, so that the best section for comparison would be one which showed a marked change in maximum lift with Reynolds number. The selection was made by the technical staff of the National Advisory Committee for Aeronautics, who chose the section N.A.C.A. 0012. Subsequently the same aerofoil was used for the roughness tests. This aerofoil and the R.A.F. 34 are both very suitable for measurements of minimum drag as they both have very small moments about the quarter chord point at low angles of incidence, an important feature in the determinations of drag in the Compressed Air Tunnel as these are obtained by the subtraction of readings taken about the so-called drag and moment axes. For aerofoils having a large  $C_{m_0}$ , these readings are frequently of the same order and the accuracy of minimum drags is small.

A preliminary note of the results of the effects of surface roughness on the aerofoil N.A.C.A. 0012 was circulated to the Aeronautical Research Committee.

2. *Aerofoil sections.*—N.A.C.A. 0012 is a symmetrical section of 12 per cent. thickness, with the maximum ordinate 0·3c aft of the leading edge. The profile is determined by the equation<sup>7</sup>

$$\pm y = 0\cdot17814 \sqrt{x} - 0\cdot07560 x - 0\cdot21096 x^2 + 0\cdot17058 x^3 - 0\cdot06090 x^4$$

where  $y$  is the distance of the surface from the line of symmetry and  $x$  is the distance from the leading edge. The dimensions are given in Table 1, in terms of the chord.

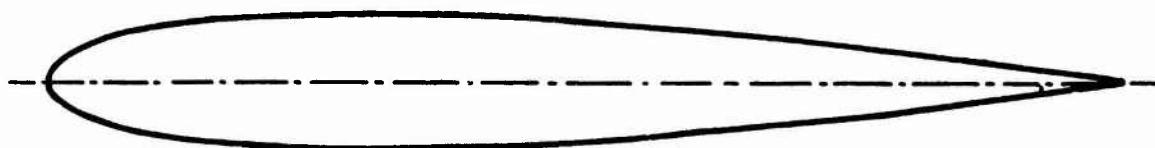

FIG. 1.—N.A.C.A. 0012.

TABLE 1

N.A.C.A. 0012

$x$	0	0·0125	0·025	0·05	0·075	0·10	0·15	0·20

R.A.F. 34 is based on a Joukowski section with 0·02c centre line camber and having a reflexed trailing edge<sup>8</sup>. The centre line equation is

$$y = 0\cdot02065 x(1-x)(7-8x).$$

The maximum thickness is 12·65 per cent. at a distance 0·3c from the leading edge. This section is designed to have no moment about the quarter chord point. Table 2 gives the profile of the section.

3. *Aerofoils and surfaces.*—The two aerofoils were rectangular in plan, of aspect ratio 6, span 4 ft., chord 8 in. Measurements on the aerofoils showed that errors in the manufacture were usually not greater than  $\pm 0\cdot001$  in. The two aerofoils were hand finished for the normal tests, but not polished. Some measurements made in the Engineering Department showed that there were scratches of a maximum depth of 0·0001 in., but that in general the surface irregularities were considerably less than this. The N.A.C.A. 0012 aerofoil was of steel, the R.A.F. 34 of aluminium.

The surfaces were roughened by painting with a paste made by mixing carborundum powder with a suitable lacquer. It is almost impossible to specify the roughness, but the degree of uniformity attained by this process is illustrated in Fig. 3, where microphotographs of the surface are shown for the two roughened conditions of test. The grades of carborundum powder used were FF and FFF, the average size of particles being about 0·001 in. and 0·0004 in. respectively. The particles were

found to adhere perfectly throughout the tests. An attempt was made to improve the hand finished aerofoil by chromium plating the N.A.C.A. 0012 model to a thickness of 0.001 in. This process made a slight improvement, but it is doubtful if the plating did more than round off small scratches, as irregularities could still be seen on the surface after plating.

The aerofoil R.A.F. 34 was roughened with FF carborundum powder (0.001 in.) only. After tests had been made with the entire surface roughened, the lacquer and carborundum was removed from the forward half of the upper and lower surfaces and the aerofoil tested with the back-half roughened.

It is proposed to improve the surface of an aerofoil by hand polishing to as fine a surface as possible and to repeat the tests on this aerofoil.

*4. Range of experiments.*—The hand finished N.A.C.A. 0012 aerofoil was tested over the whole range of Reynolds numbers from  $0.164 \times 10^6$  to  $7.20 \times 10^6$ , the pressure in the tunnel being varied from 1 to 25 atmospheres and the wind speed from 17 to 80 ft./sec. Lift, drag, pitching moment and centre of pressure coefficients are given in Table 3 for a range of  $\alpha$  from  $-3^\circ$  to  $+28.5^\circ$  for low values of  $R$  and from  $0^\circ$  to  $28.5^\circ$  for high values of  $R$ .

Tests over the full range of angles on N.A.C.A. 0012 roughened with FFF and FF carborundum were only carried out at three Reynolds numbers, with measurements of lift near maximum lift at two additional values of  $R$ . The results for these two surface conditions are given in Tables 4 and 5 respectively.

A comprehensive series of tests, similar to that on the hand finished aerofoil, was made on N.A.C.A. 0012 with chromium plated surface, the results of which are given in Table 6. In addition, with this surface condition, measurements were made with the aerofoil inverted in order to determine the corrections due to any slight asymmetry of the model. A small correction on moment was found and this has been applied to all the results on the N.A.C.A. 0012 aerofoil. The correction was  $-0.0006$  on the calculated values of  $C_m$ .

Results on the aerofoil R.A.F. 34, hand finished, are given in Table 7. These are taken from R. & M. 1706<sup>5</sup> with an additional set taken at a high Reynolds number to get further information on the maximum lift.

Tables 8 and 9 give the results obtained for R.A.F. 34 with the back-half roughened with FF carborundum and the entire surface similarly roughened.

The values of pressure, Reynolds numbers and speed for the sets given are tabulated below.

In addition to these results, a number of observations of  $C_{D\min}$  were made on these aerofoils with the various surface conditions for a range of pressures and speeds. The results, with details of the appropriate values of R, pressure, V and  $\rho V^2$  are given in Tables 10-13 for N.A.C.A. 0012, and in Tables 14-16 for R.A.F. 34. The results are shown in Figs. 11 and 12 for the two sections.

All the results have been corrected for tunnel interference.

5. *Routine tests on N.A.C.A. 0012.*—The values of the lift coefficient, with increasing incidence, near maximum lift have been plotted in Fig. 4 for the hand finished aerofoil. The maximum lift increases rapidly with Reynolds number from 0.81 at  $R = 0.164 \times 10^6$  to 1.36 at  $R = 2 \times 10^6$  and then slowly to 1.425 at  $R = 7.2 \times 10^6$ . This is well brought out by curve B in Fig. 9 where the maximum lift coefficient is plotted against Reynolds number. There is a large drop in  $C_L$  above the stall and the drop becomes more and more abrupt as R increases. The value of  $C_L$  just above the stall increases with R to a maximum at  $R = 2 \times 10^6$  after which it decreases as R continues to increase.

On a number of aerofoils, as the angle of incidence is decreased from above the stall, the stalled condition persists below the normal stalling angle: this applies particularly to aerofoils having a large drop in lift at the stall. For such aerofoils, there is a region of incidence where either flow can be obtained and where there are alternative readings of lift, drag and moment coefficients; the values obtained depending on whether the particular angle is approached from below or from above the stall. In Fig. 5 the lift coefficient with incidence decreasing has been plotted

The curves are shown broken in the region where the lift differs from that obtainable with increasing incidence.

FIG. 5.—Lift on N.A.C.A. 0012 with Decreasing Incidence.  
Aspect Ratio 6, Chord 8 in.

for comparison with Fig. 4. Where the readings differed from those for increasing incidence, the curves have been drawn with broken lines. Alternative values were obtained at all values of  $R$  except the lowest, but it was sometimes difficult to find them where they existed. For example, at  $R = 5.52 \times 10^6$ , it is obvious that the maximum value of  $C_L$  at  $\alpha = 20.2^\circ$  was missed as the incidence was increased; the two sets of values were found for the readings about the drag and moment axes. Only the drag is given in the Tables at this point as both lift and drag are necessary for the computation of  $C_m$ . Similarly, no reading of  $C_L$  for decreasing incidence could be obtained at  $\alpha = 18.6^\circ$  for  $R = 3.94 \times 10^6$  or at  $\alpha = 15.4^\circ$  for  $R = 0.98 \times 10^6$ , though duplicate readings were found about the other axes in these cases also. About  $R = 1 \times 10^6$  to  $R = 1.5 \times 10^6$  the changes in  $C_L$  with  $R$  are very large just above the stall. With decreasing incidence there seem to be indications of two stalls in that neighbourhood.

The lift curves for N.A.C.A. 0012 with chromium plated surface are very similar to those for the hand finished aerofoil except that there is a more sudden transition above the stall from the curves for low to those for high values of  $R$ . The maximum value of  $C_L$  at  $R = 5.56 \times 10^6$  with increasing incidence was obtained in this case—it could not be found for the hand finished aerofoil. The absolute maximum reached was 1.445, 0.020 higher than for the first aerofoil.

Table 3 includes a set of observations at  $R = 1.47 \times 10^6$  taken at 22.8 atmospheres, but these results have not been plotted in the figures as this set is thought to be less reliable than the one at  $R = 1.44 \times 10^6$  at 4.8 atmospheres pressure. The wind speed for the high pressure set was 17.1 f./s. and results in the Compressed Air Tunnel are not very trustworthy for low wind speeds. The lift curves for N.A.C.A. 0012 with the two degrees of surface roughness are given in Figs. 6 and 7. They are only plotted in the neighbourhood of maximum lift and all the cases examined show the phenomenon of double flow.

The diagrams of drag against lift are shown in Fig. 8 up to  $C_L = 0.4$ . The minimum drag decreases from 0.012 at  $R = 0.164 \times 10^6$  to 0.0065 at  $R = 1 \times 10^6$  and  $R = 2 \times 10^6$  and then increases with  $R$  to 0.0078 at  $R = 7.2 \times 10^6$ . The form of the polar curves varies somewhat with  $R$ , the profile drag being more nearly constant for high values of  $R$  than for the low. The curve for  $R = 0.164 \times 10^6$  has a distinctly different shape from the others, due to high lift coefficients near  $4^\circ$  and  $6^\circ$  incidence. These results have been repeated showing that the irregularity is not due to errors of observation.

The curve for the induced drag  $0.0555 C_L^2$  has been included in the diagram.

The moment coefficient shows a marked scale effect at small angles of incidence, and the slope of the moment curve at the origin decreases as  $R$  increases up to  $R = 1 \times 10^6$ , after which it remains sensibly constant.

6. *Effect of roughness on maximum lift.*—In Fig. 9 the maximum lift coefficients for the aerofoil N.A.C.A. 0012 are plotted against Reynolds number, the full lines representing maximum lift with increasing incidence and the broken lines that with incidence decreasing. Owing to the uncertainties in obtaining the alternative readings, the broken line curves cannot be considered as accurate as the full lines. The effect of surface roughness is immediately evident and makes itself felt on maximum lift at about the same value of Reynolds number as does the effect on minimum drag (see Fig. 10). The maximum lift appears to increase uniformly with increase in  $R$  up to a definite value of  $R$ , depending on the degree of surface roughness, and then to remain practically constant as  $R$  increases further. The sudden change in the form of the curve (B in Fig. 9) for the hand finished aerofoil points to the possibility that this aerofoil was rough for high values of  $R$ , and to the desirability of testing a model made as smooth as can be obtained. As the maximum lift of the majority of aerofoils tested in the Compressed Air Tunnel has been of the order of  $C_L = 1.4$  at  $R = 7 \times 10^6$ , it suggests that this limit may be due to small roughnesses on the surface common to all these aerofoils, and this idea is strengthened by the increase of about 5 per cent. on  $C_{L_{max}}$  which was effected by chromium plating the surface (curve A in Fig 9).

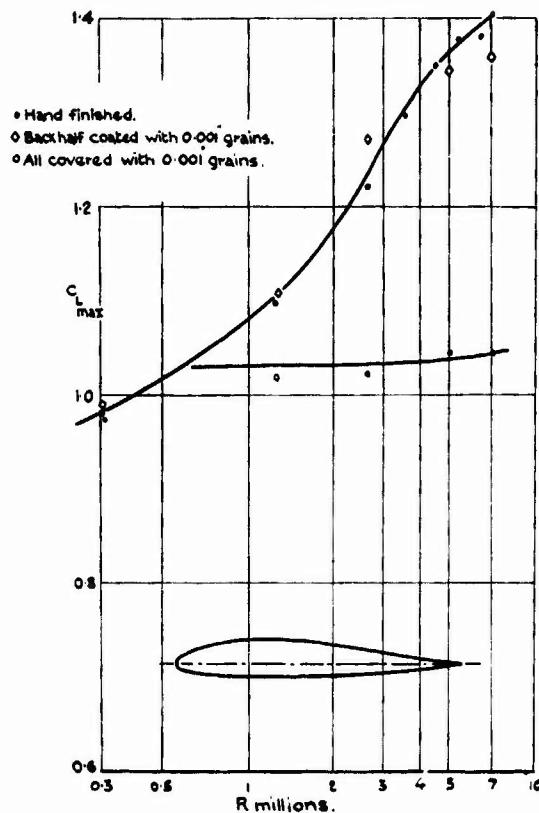

Hand finished aerofoil and aerofoil coated with carborundum powder.

FIG. 9.—Maximum Lift on N.A.C.A. 0012. 8 in. Chord.

Roughening the surface with FFF carborundum (0.0004 in. grains) lowered the maximum lift by some 15 per cent., to 1.20 from 1.42 for the hand finished aerofoil. The coarser roughening with FF carborundum (0.001 in. grains) reduced the maximum lift coefficient to 1.15, a reduction of 20 per cent. on that of the aerofoil with the usual finish. A comparison of this diagram with that for R.A.F. 34 (Fig. 10) shows that the rate of increase of  $C_{L_{\max}}$  at the lower values of  $R$  is much greater for the symmetrical aerofoil N.A.C.A. 0012 than it is for ordinary aerofoils of the same thickness ratio. The aerofoils previously tested do not reach a value of 1.4 for  $C_{L_{\max}}$  until  $R$  gets to a value of  $4 \times 10^6$  or higher, whereas the N.A.C.A. 0012 attains that value at  $R = 2 \times 10^6$ .

Fig. 10 gives the maximum lift curves for the aerofoil R.A.F. 34. Roughening the surface of this aerofoil with FF carborundum has a much greater effect on  $C_{L_{\max}}$  than it had on N.A.C.A. 0012. The curve for the roughened aerofoil leaves

Hand finished aerofoil and aerofoil coated with carborundum powder.

FIG. 10.—Maximum Lift on R.A.F. 34. 8 in. Chord.

that for the hand finished one at about  $R = 1 \times 10^6$ , as it did for N.A.C.A. 0012, but the lift coefficient there is considerably lower than for the symmetrical aerofoil. The maximum lift falls from 1.40 to 1.04 when the surface is roughened, a loss of 26 per cent. in  $C_{L\max}$ .

The effect of roughening the back-half of the wing makes no appreciable difference to the maximum lift up to  $R = 7 \times 10^6$ , though there is an indication that the maximum lift may be beginning to fall off at the highest values of  $R$ .

As one aerofoil was of steel and the other of aluminium, it may be that the surfaces of the two aerofoils hand finished are not the same, though the fact that the minimum drag curves are very similar indicates that they are of the same order of smoothness aerodynamically.

**7. Effect of surface roughness on minimum drag.**—The results of the tests on minimum drag are given in Tables 10–16 and they are plotted against Reynolds number in Figs. 11 and 12 for N.A.C.A. 0012 and R.A.F. 34 respectively. The diagrams also include the minimum values of  $C_D$  from the sets taken over the full range of incidence, taken from Tables 3–9. In order to determine the curves as

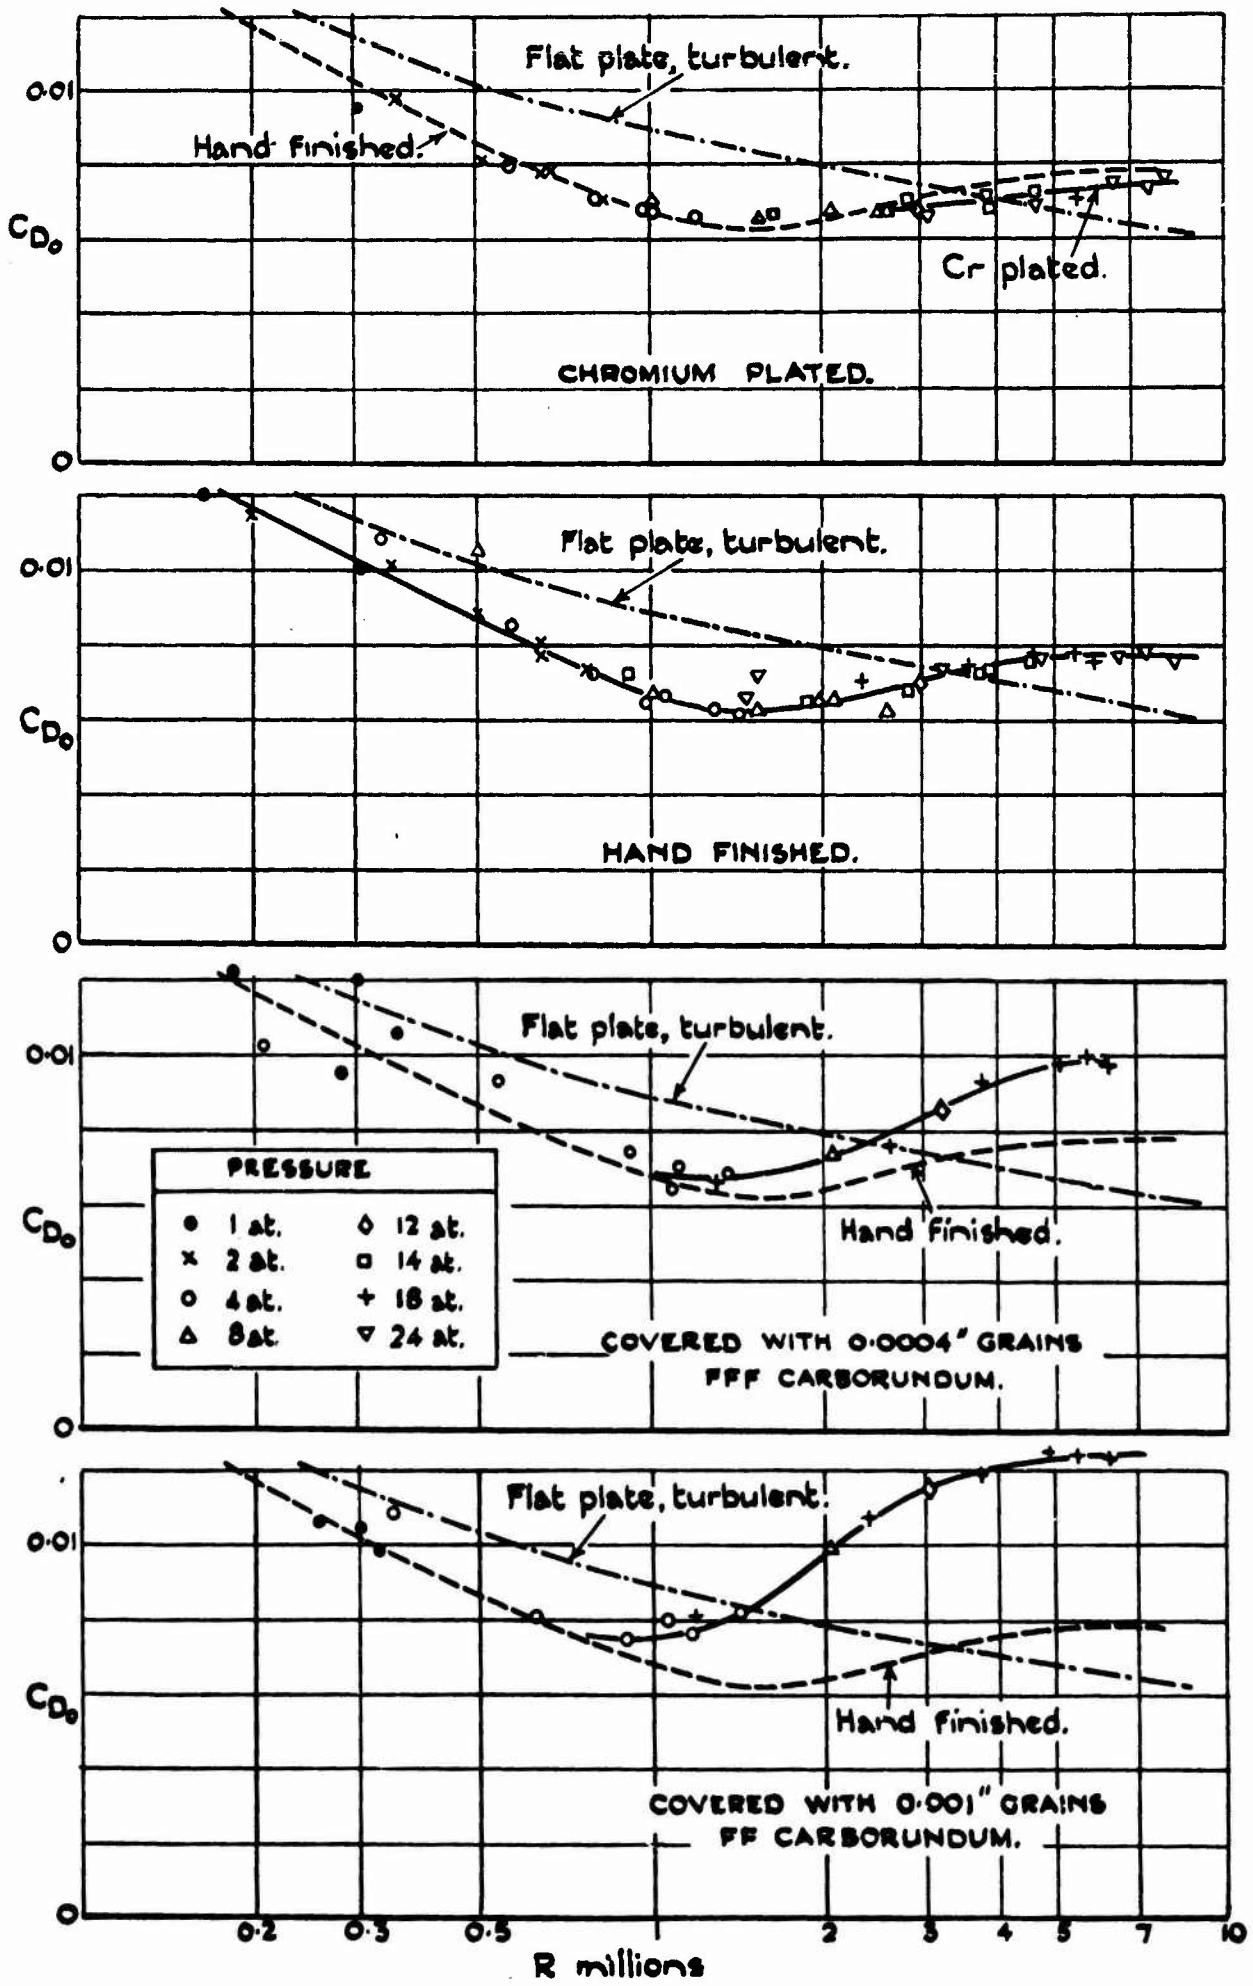

FIG. 11.—Minimum Drag of N.A.C.A. 0012 with Various Degrees of Surface Roughness.  
Aspect Ratio 6. Chord 8 in.

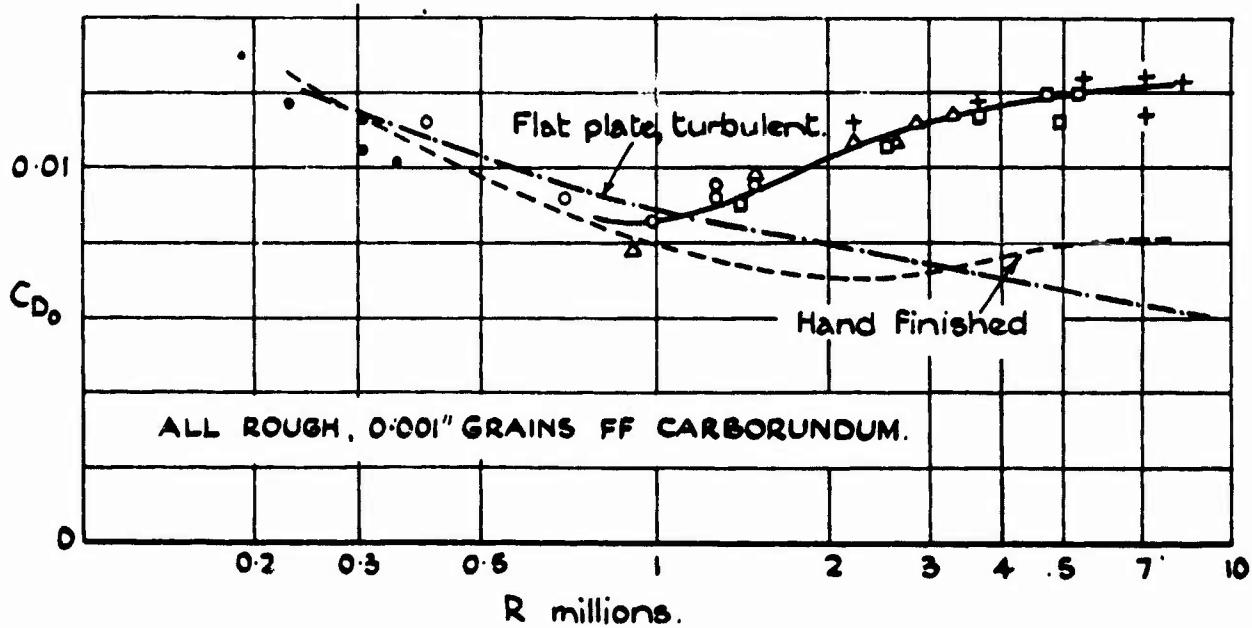

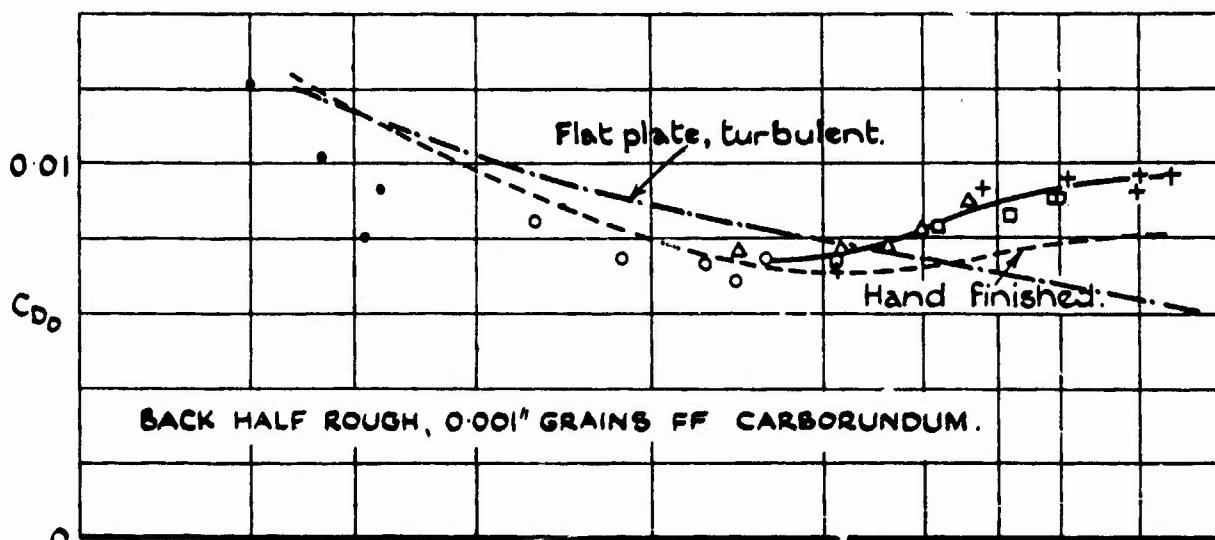

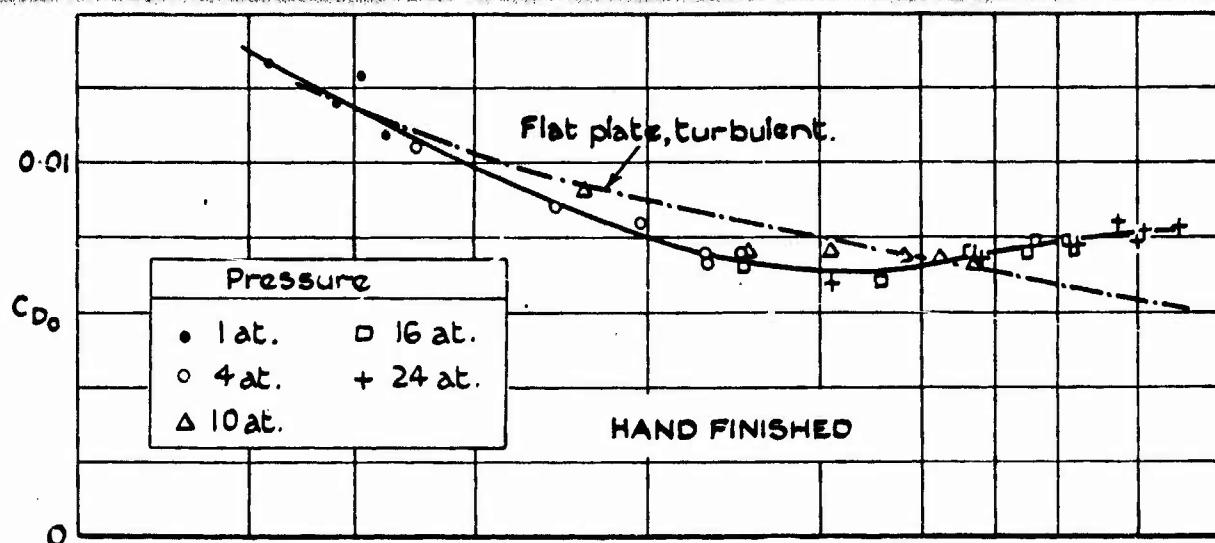

FIG. 12.—Minimum Drag of R.A.F. 34. Aspect Ratio 6. Chord 8 in. Aerofoil Hand Finished and Coated with Carborundum (FF) Powder. 0.001 in. Grains.

(33010)

fully as possible, readings were taken at a number of wind speeds for each tunnel pressure so that there would be an overlapping of points. The system of points chosen in the diagrams has one type of point for each tunnel pressure and in general, at any pressure, more weight has been attached to points taken at high wind speeds than to those taken at low speeds.

Minimum drag and minimum profile drag agree on the symmetrical aerofoil but not on R.A.F. 34. In the latter case, it is minimum drag and not minimum profile drag that is plotted in the figures, as the observations at numerous Reynolds numbers were taken in the neighbourhood of minimum drag and did not cover a large enough range necessarily to include minimum profile drag.

In each diagram, the curve for the hand finished aerofoil has been included as a standard and the curve for turbulent skin friction of a smooth plate has been drawn in.

For the N.A.C.A. 0012 aerofoil it is seen that roughening, to the extent tried, has no effect on the minimum drag up to a Reynolds number of  $1 \times 10^6$ , but after that the curves for the roughened aerofoils break away from that for the hand finished aerofoil and the Reynolds number, at which the divergence occurs, becomes less as the roughness increases. After the divergence the minimum drag increases rapidly with Reynolds number up to a constant value, the greater the roughening the greater the rise in  $C_{D \text{ min.}}$  at high Reynolds numbers. These results agree with the predictions of Prandtl and Schlichting<sup>2</sup> as to the point of the divergence and with Fage's<sup>9</sup> calculations of the amount of the increase. The increase at the highest Reynolds number is about 26 per cent. for the FFF roughening (0.0004 in. grains) and 59 per cent. for the coarser roughening FF (0.001 in. grains). Fage's predictions for the increases at  $R = 9.4 \times 10^6$  for these roughnesses are 28 per cent. and 64 per cent. respectively.

The curves for R.A.F. 34, shown in Fig. 12, give similar results. The divergence for the coarse roughening occurs at the same value of  $R$  as it did for the symmetrical aerofoil and the increase is of the same order (53 per cent.). Roughening only the back-half of the aerofoil causes the divergence to happen at a higher Reynolds number and causes considerably less than half the increase in minimum drag, as would be expected, since the boundary layer thickness would be larger by the time it reached the roughened part of the aerofoil.

The curve for the turbulent skin friction of a smooth flat plate has been added to show that the flattening of the curve for the hand finished aerofoil is not, as might be supposed, due to insufficient smoothness about  $R = 1 \times 10^6$ , but to the fact that the drag results lie on a transition curve. As this curve is above the turbulent skin friction curve at high values of  $R$ , the aerofoil may not have been aerodynamically "smooth" for those values. This is borne out to some extent by the curve for the chromium plated aerofoil, where the minimum drag has been reduced 5 per cent.

8. *Profile drag.*—The curves for profile drag of the aerofoil N.A.C.A. 0012 at lift coefficients of 0, 0·2, 0·4, 0·6, 0·8 are plotted against Reynolds number in Fig. 13, and those for R.A.F. 34 in Fig. 14. The full heavy lines are the curves for the aerofoil with hand finished surface. The forms of the curves are different for the two aerofoils except for low values of  $C_L$ .

The values of the profile drag for the rougher surface conditions are also shown. For the symmetrical aerofoil, they were only found at three Reynolds numbers, about 0·3, 1·0 and 5·5 millions. These values are shown in Fig. 13 by points joined up by thin lines for roughening with FFF carborundum and by heavy chain-dotted lines for FF carborundum. The exact form of this curve is unknown between  $R = 1 \times 10^6$  and  $R = 5\cdot5 \times 10^6$ . It is probable, however, that the curves drawn are fairly correct, as they agree with those in Fig. 14 for R.A.F. 34 for which a sufficient number of observations was taken to establish the form of the curves.

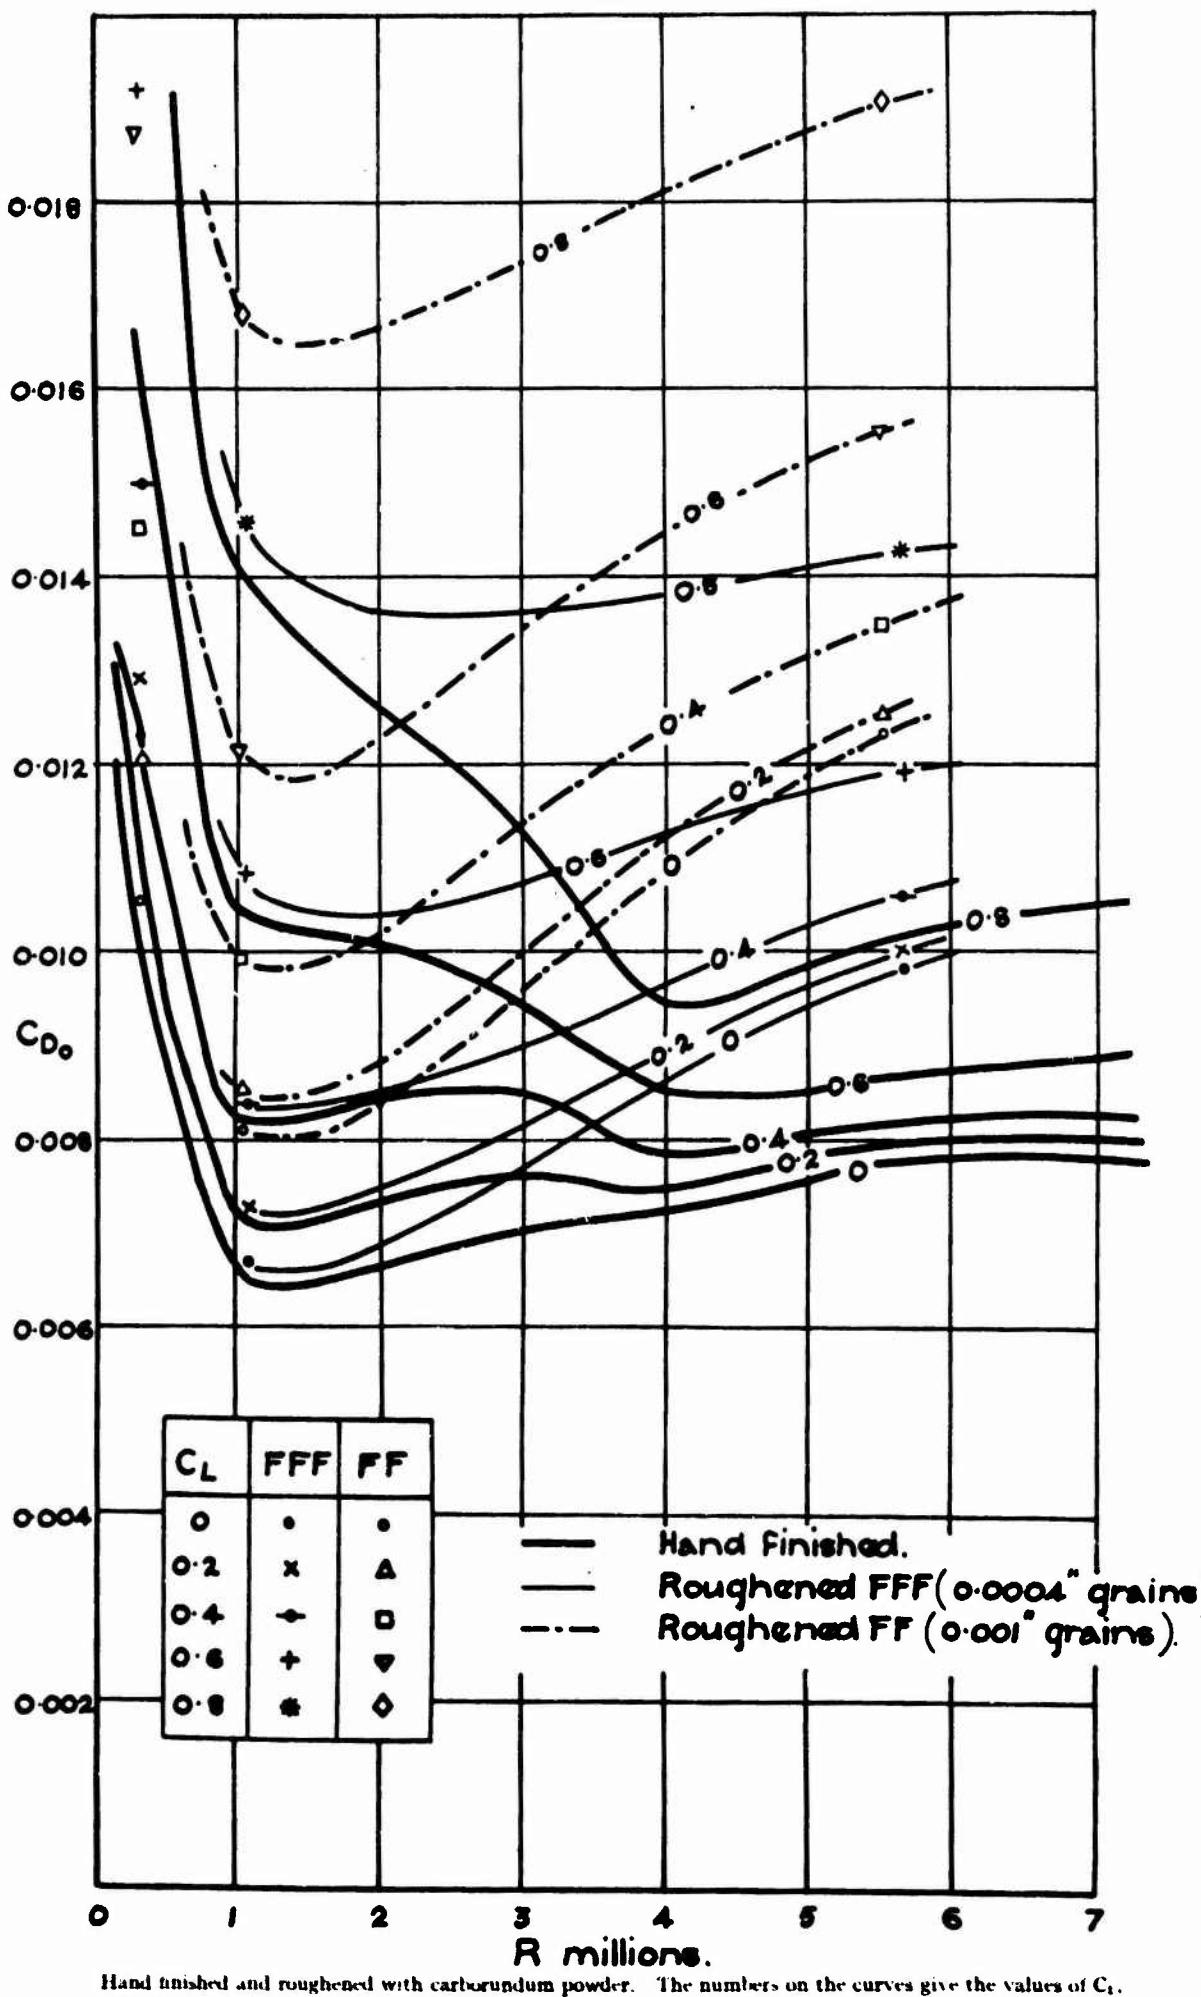

Curves for the chromium plated aerofoil have not been included, as they would lie close to those for the hand finished aerofoil.

9. *Conclusion.*—From a practical point of view, the degrees of roughness used on the model are perhaps rather great, as they correspond to distributed excrescences of 0·01 in. and 0·004 in. on an actual wing of moderate chord. But, as mentioned above, the main object of the experiments was to test the validity of the application of the deductions from the pipe work to an aerofoil. The result of most practical utility is that the Reynolds number, at which divergence from the smooth drag curves occurs, agrees fairly closely with the pipe predictions, and therefore that these can be used to establish a measure of maximum roughness which will not affect the drag at any given Reynolds number. Actual wings and bodies should be made as smooth as this procedure indicates, but there is no necessity to produce a more highly finished surface. The smoothness desirable will be greater with greater speed and also with greater chord. The table below has been compiled from results given by Prandtl<sup>2</sup> in order to provide a guide to the degree of roughness permissible.

Reynolds number in millions.	Thickness of permissible excrescences in millionths of the chord.
1	81·0
2	44·0
5	19·0
10	10·0
20	5·4
50	2·3
100	1·2

*Note.*—Near  $R = 10^7$ , which is the interesting region in practice, a rough rule is

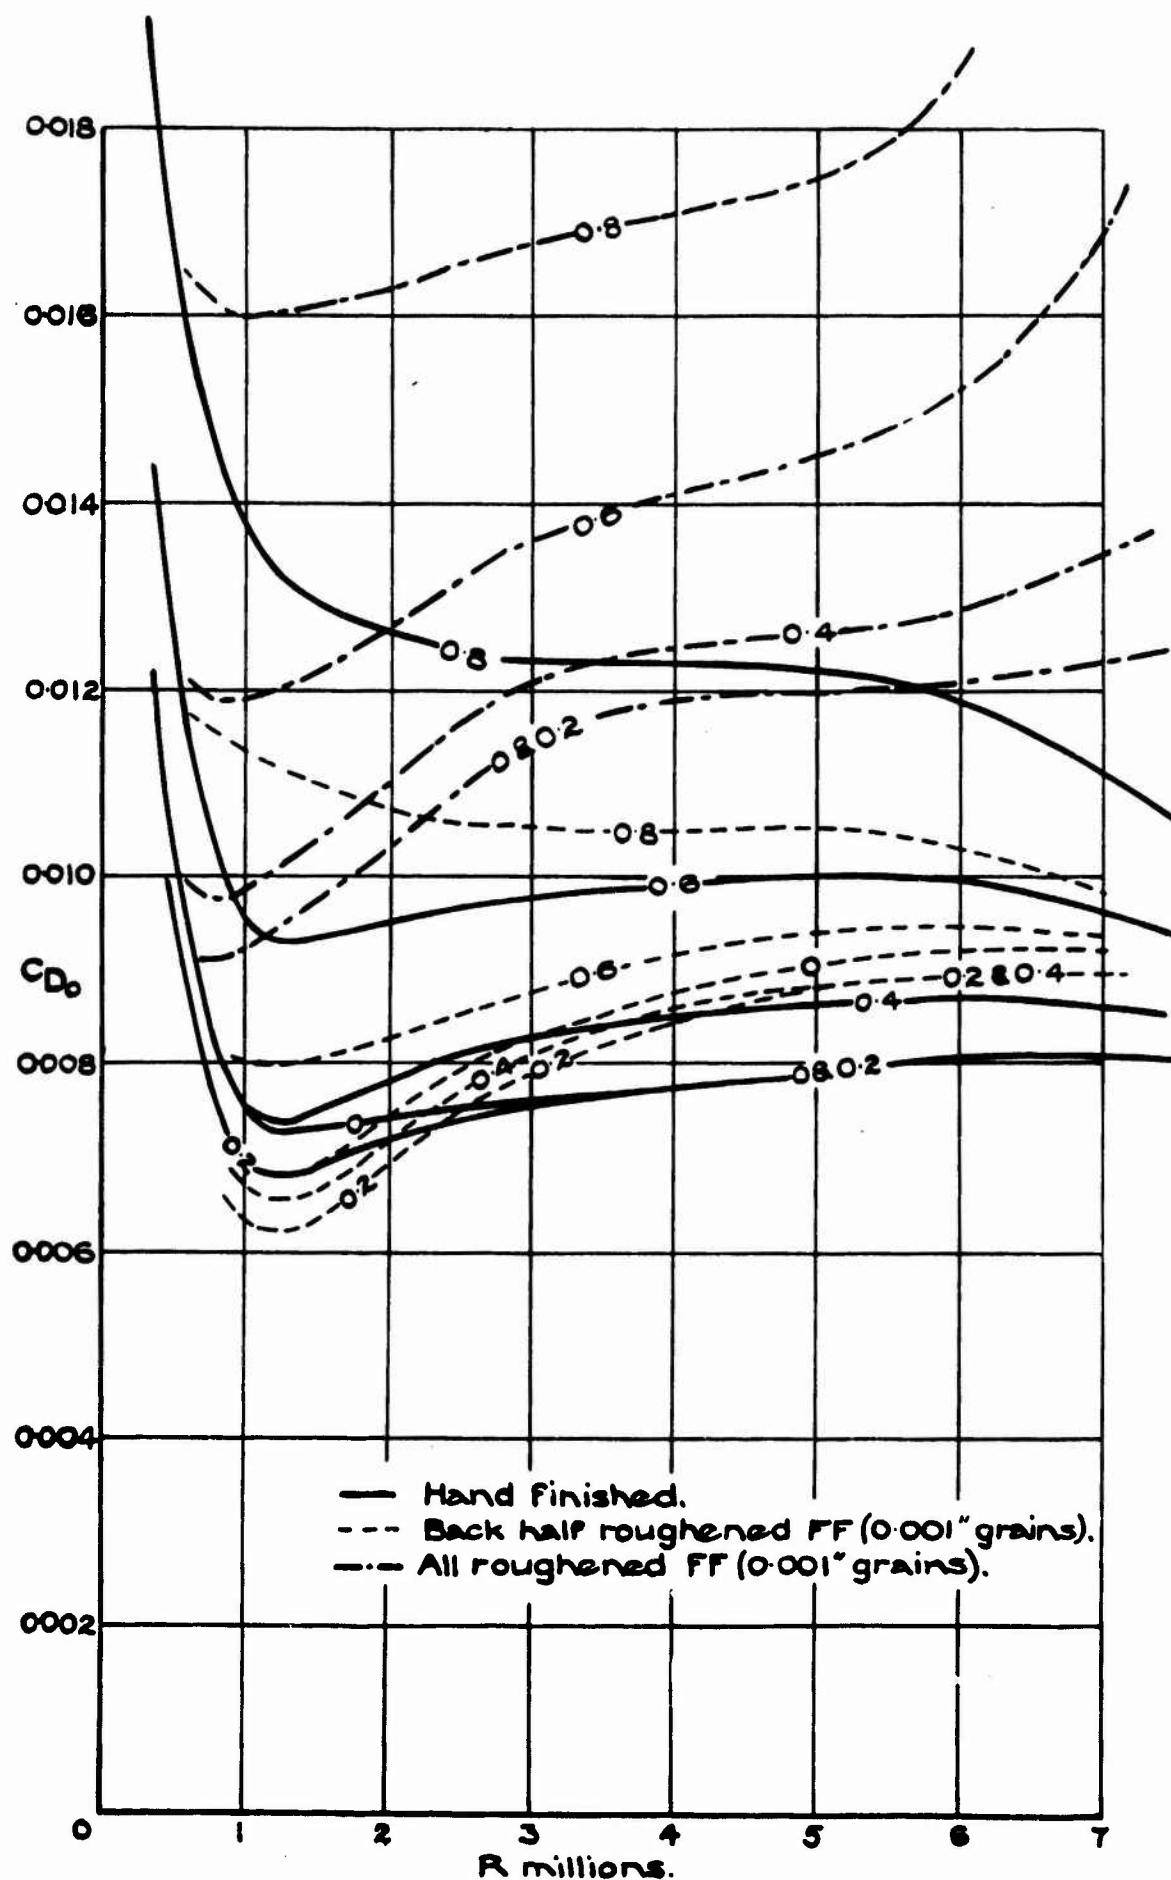

$$\text{Thickness in millionths of chord} = \frac{100}{R \text{ in millions}}$$

Hand finished and roughened with carborundum powder. The numbers on the curves give the values of  $C_L$ .

The numbers on the curves give the value of  $C_L$ .

FIG. 14.—Profile Drag of R.A.F. 34 at Various Values of  $C_L$  and Reynolds Number.  
Aspect Ratio 6. Chord 8 in.

It must be remembered that this applies to a distributed roughness such as is produced by closely spaced irregular particles like sand or carborundum grains. It does not follow that more rounded irregularities such as are produced by the threads of a fabric will produce the same results for the same variation of height, nor can the results be applied to widely spaced irregularities such as rivet heads; the determination of such effects would have to be tested separately.

The effect of surface roughness is also important on maximum lift, but only on the front part of the surface. If the roughness is aft of the breakaway point, its effect will not be marked. The exact proportion of the upper surface for which extreme smoothness of the wing is important will have to be determined by further experiment.

The experiments have established that surface roughness has no effect on minimum drag or maximum lift for Reynolds numbers up to a value depending on the degree of roughness. Above that value, surface roughness increases the drag and decreases the maximum lift of an aerofoil to an extent which increases as the roughness increases.

The authors wish to express their indebtedness to Messrs. A. H. Bell, A. F. Brown and E. Smyth, who took their full share in all the work described in this report.

## SYSTEM OF AXES

Axes	Symbol Designation Positive direction	$x$ longitudinal forward	$y$ lateral starboard	$z$ normal downward
Force	Symbol	$X$	$Y$	$Z$
Moment	Symbol Designation	$L$ rolling	$M$ pitching	$N$ yawing
Angle of Rotation	Symbol	$\phi$	$\theta$	$\psi$
Velocity	Linear Angular	$u$ $p$	$v$ $q$	$w$ $r$
Moment of Inertia		A	B	C

Components of linear velocity and force are positive in the positive direction of the corresponding axis.

Components of angular velocity and moment are positive in the cyclic order  $y$  to  $z$  about the axis of  $x$ ,  $z$  to  $x$  about the axis of  $y$ , and  $x$  to  $y$  about the axis of  $z$ .

The angular movement of a control surface (elevator or rudder) is governed by the same convention, the elevator angle being positive downwards and the rudder angle positive to port. The aileron angle is positive when the starboard aileron is down and the port aileron is up. A positive control angle normally gives rise to a negative moment about the corresponding axis.

The symbols for the control angles are :-

- $\xi$  aileron angle
- $\eta$  elevator angle
- $\eta_T$  tail setting angle
- $\xi$  rudder angle
